

Information Systems Curriculum Using an Ecological Model

Arthur Tatnall

Victoria University, Australia

Bill Davey

RMIT University, Australia

INTRODUCTION

To those of us involved in research and teaching in information systems (IS), it is clear that curriculum innovation and change is complex, and anything but straightforward. The amount of control that individual IS academics have over the curriculum varies between universities. In some cases there is complete control over curriculum content whereas in others just control over delivery with content determined externally. This article concentrates on the former situation but still has some relevance to the latter. All curriculum innovation is complex (Fullan, 1993) due to the involvement of a large number of human actors, but in information systems curriculum change this is particularly so due to the need to consider the part played by such non-human actors (Latour, 1996) as the technology itself.

We will argue that if you want to understand *how* IS curriculum is built, you need to use models and metaphors that relate to how people interact with each other, with the environment, and with non-human artifacts. One such approach is provided by the ecological metaphor described in this article in which we argue that systems of education may be seen as ecosystems containing interacting individuals and groups. The interactions between these will sometimes involve co-operation and sometimes competition, and may be interpreted in terms of these forces along with mechanisms for minimizing energy expenditure. In this article we will examine the application of this metaphor to curriculum change in information systems.

BACKGROUND

Nordvall (1982) identifies several models for curriculum change that he suggests all have relevance, in the higher education context, at the subject, course, and institutional levels. These are:

- Research, development, and dissemination models
- Problem solving models; social interaction models
- Political and conflict models
- Diffusion, linkage, or adaptive development models

Models of change based upon a process of research, development, and dissemination (RDD) are probably the most common way of attempting an explanation of the process of curriculum development (Nordvall, 1982). In models like this, relying on logical and rational decisions, curriculum change depends on the use of convincing arguments based on programs of research. A rational and orderly transition is then posited from research to development to dissemination to adoption (Kaplan, 1991). These could then be considered as “manufacturing models” as they follow a fairly logical and straightforward mechanical approach with one thing leading directly to another and do not allow for or consider other influences such as those due to human interactions. If we were to accept a manufacturing model like this, then we might expect some curriculum outcomes to be consistently apparent across the world:

- As research would have shown that several specific programming languages were much more widely used and better to teach than others, all courses requiring programming would use just these few languages, and there would be no arguments regarding the best language to teach.
- As research would show the advantages of object-oriented methodologies all computing courses would teach only these and ignore other approaches.
- The content of courses around the world would be designed to achieve similar goals and outcomes, and contain similar content.
- Research would show the ideal method of teaching computing concepts and issues and classroom delivery of content would be moving toward this researched ideal. Everyone would then use these ideal delivery methods.

It is easy to illustrate that these predictions are not borne out in fact, as programs of study show wide variance within any given country and around the world. Many different programming languages and development methodologies are used, and a wide variety of techniques is adopted for classroom delivery. Some innovations seem to be accepted world wide, but many are accepted only locally. We will here

provide an alternative model that we believe better explains how IS curriculum is really developed.

Metaphors and Models

Before proceeding, however, we need to caution the reader on the limitations of models and metaphors. The dictionary describes a metaphor as a term “applied to something to which it is not literally applicable, in order to suggest a resemblance” (Macquarie Library, 1981, p. 1096). Metaphors are useful, not in giving a literal interpretation, but in providing viewpoints that allows us to relate to certain aspects of complex systems.

We contend that most curriculum models and metaphors are too simplistic to allow a useful view of a curriculum development as a complex system involving human and non-human interactions. In this regard, ecological model offers two main advantages:

- A way of allowing for the inclusion of complexity
- A new language and set of analytical and descriptive tools from the ecological sciences

AN ECOLOGICAL MODEL OF CURRICULUM CHANGE

In ecology organisms are seen to operate within a competitive environment, which ensures that only the most efficient of them will survive. In order to survive, they behave in ways that optimize the balance between their energy expenditure and the satisfaction they obtain from this effort. These two key principles underlie the discipline of ecology, which is concerned with the relationship of one organism to another and to their common physical environment (Case, 2000; Townsend, Harper, & Begon, 2000). Habitat, ecological niches, and the exploitation of resources in predator-prey interactions, competition, and multi-species communities (Case, 2000) are all important considerations in ecology.

We have argued (Tatnall & Davey, 2002, 2003, 2004) that these ideas correspond to the process of curriculum development in that an educational system may be seen as an ecosystem and that the interactions within this can then be analysed in terms of ecological concepts such as competition, co-operative behavior, and niche-development. Curriculum change can be interpreted in terms of mechanisms for minimizing energy expenditure and decisions that individuals make about whether to cooperate or to compete.

In information systems curriculum development we should thus look at all the factors, both human and artifact, to see which could be expected to compete, and which to cooperate to become part of the surviving outcome. A non-human stakeholder such as a development tool or

methodology must cooperate with the environment, compete successfully, or die out. This may mean a new curriculum element becomes incompatible with an old element and so replaces it. Alternatively it may mean that two new design tools can be used together, or that a particular curriculum element is compatible, or perhaps incompatible, with the desires and interests of a particular faculty member.

Ecological metaphors have been used in areas other than biology and IS curriculum change. An ecological framework has been used quite successfully in other areas including mathematics curriculum (Truran, 1997) and a study of the effects of violence on children (Mohr & Tulman, 2000). Ecology as a framework tells us to expect progress of a task through cooperative or competitive behaviors of the animate and inanimate factors in the environment. A factor that cannot compete or cooperate is inevitably discarded.

Ecosystems and Complexity

An ecosystem contains a high degree of complexity due to the large number of creatures and species living in it, as well as the variety of interactions possible between each of these. The “ecosystem” represented by the curriculum in a university information systems department contains (at least) the following “species”: lecturers, researchers, students, professional bodies, university administrators, and representatives of the computer industry. The “environment” also contains many inanimate objects relevant to the formation of the curriculum, including computers, programming languages, textbooks, lecture rooms, analysis and design methodologies, networks, laboratories, programming manuals, and so on.

Curriculum development can be seen as attempting to introduce change within an ecosystem. The problem, of course, is the large number of interested parties that must be contended with before change can be implemented. Curriculum development is more complex than resolving the conflicting needs of students, employers, academics, and the academy. There is ongoing conflict between many things such as educational philosophies, pedagogical preferences, perceived resource constraints, and personal issues. To investigate the interrelationships between these entities we will look now at competition, co-operation, niche formation, and energy expenditure.

Competition

Competition in nature can occur both within and between species. In many species the males compete with each other for mates, while different species of fish compete for the best feeding areas. In IS curriculum we see many examples of competition, some of which are useful in determining the “fit-test” topics and techniques best suited for survival (Darwin, 1859) in the curriculum, while others involve time-wasting clashes of personality between academics.
