

Software Process Improvement for Web-Based Projects Comparative View

S**Thamer Al-Rousan***Isra University, Pakistan*

INTRODUCTION

In the last two decades, there have been a significant increase on the expectations and demand of Web-based application due to the influence of the World Wide Web on our modern economy (Pressman, 2004). At the same time, the development, deployment and maintenance processes of the web-based systems which have become more and more complex and difficult to manage, have not progressed at a sufficient rate to meet these demand and expectations (Cardoso, 2007).

Many developers of web-based projects do not take into concern the unique requirements and characteristics of Web applications. They fail to realize that characteristics and requirements of web-based systems considerably different from that of traditional software, and so does their development (Alrifai, 2008). Hence, many developers conduct web applications in an ad hoc manner, and fail to adopt sound design methodologies, resulting in poor quality web systems and applications. A survey by the Cutter Consortium (2006) shows that failure to meet business needs (84%), project schedule delays (79%), and budget overruns (63%), lack of functionality (53%) and poor quality of deliverables (52%) are the main problems cited by the stakeholders of such applications.

In finding solutions to the problems of web-based application development, there has been an increasing pressure on the Web-based application industry. The search for solutions to improve Web-based software development has continued for many years and Web-based applications organizations are now realizing that one of their

fundamental problems is the inability to effectively manage the Web-based applications development process (Sulayman & Mendes, 2011). Software Process Improvement (SPI) has been recognized as an efficient and effective way for organizations to improve their quality of the software they develop and the productivity with which they work with. For this, SPI is an essential tool for improving Web-based applications development process (Sulayman & Mendes, 2011).

Process improvement in Web-based software projects is of growing concern for many reasons such as reducing cost and time, producing high quality software, and improving productivity (Smite et al., 2011). Despite the importance of SPI implementation, there is evidence that the vast majority of Web-based software development organizations are reluctant to adapt SPI models and standard because of their complexity (Abdel-Hamid & Abdel-Kader, 2011). It has been detected that improvement efforts in Web-based software projects based on process improvement frameworks which are designed for traditional software projects fails most of the time (Sulayman & Mendes, 2011).

In the absence of theoretical or empirical work examining the suitability of the traditional SPI standards and models for Web-based projects development, we believe that it is important to examine the suitability of the existing SPI standards and models for Web-based projects development process. The motivation for this study was to fill the gaps in the field of software process improvement. The main contributions of this study are:

1. Examine the suitability of the existing software process improvement models and standards for Web-based projects.
2. Increasing awareness on the importance of software process improvement in Web-based projects.

We believe that achieving these goals will lead to enrich the SPI in Web-based projects with new properties that leads to enhance the SPI projects implementation.

BACKGROUND ON WEB-BASED SOFTWARE DEVELOPMENT

There is a relatively small but a rising research on the differences between the Web-based applications and traditional software development. In general, this literature shows that the Web-based applications have certain unique inherent characteristics that make Web-based development considerably different and possibly more difficult comparing with software development (Rousan et al., 2014). The Web-based application characteristics which are usually built in shorter time-frames, serving as direct interface to various stakeholders, should meet a broad set of requirements and more than often serve a specific group of users. They are usually built from template solutions, by using coarse-grained authoring tools, which were developed by a multidisciplinary team (Ginige, 2002). These characteristics constitute the reasons why many concepts, methods, techniques, and tools of traditional software development are either insufficient to meet the needs of Web-based applications or have to be modified in order to do so (Pressman, 2004). Thus, Web-based project developers must have a reasonable understanding of the characteristics of Web-based project development and how these may affect the outcome of the project.

Web-based project development process is a complex and a demanding activity. Hence, the development of high-quality Web applications

does not occur naturally, there must be a systematic plan, complete with managing and improving the process, testing, and evaluation, to develop and implement the Web-based software project accordingly (Smite et al., 2011). Under such demanding circumstances, SPI is becoming increasingly important for Web-based software project.

RELATED WORKS AND RATIONALE OF SPI

The motivation for execution process improvement activities is to gather information as to what needs to be changed and to set up how to follow the improvements in order to reduce development cost and increase the quality of products created (Pino et al, 2008). SPI is about making things better. Unfortunately, the majority of Web-based software development organizations don't concentrate on process improvement activities. Some cases about the implementation of SPI founded in literature. A case study about the performance of SPI models in Web-based software development was proposed in (Sulayman & Mendes, 2011). Software process improvement in Web-based software development based on agile methods was proposed in (Abdel-Hamid & Abdel-Kader, 2011). The continuous improvement in the basis of the existing method was been provided by Nawazish et al. (2010). It gives some comments and suggestions that must be followed during the Web-based software development process. It concentrates on the gathering information that need to be changed, reducing the cost of development, and increasing the quality of the product produced by setting up how to follow the improvements. Salinas et al. (2012) analyze whether the practices proposed in Scrum meeting the CMMI generic and specific goals or not. They found that the CMMI is not appropriate for Web-based projects that based on scrum.

Software process Improvement is a continuing practice and must always be followed up with the analysis of actual areas of improvement. When SPI implemented effectively, the results can be
