Chapter III

Discovering Quality Knowledge from Relational Databases

M. Mehdi Owrang O., American University, USA

Abstract

Current database technology involves processing a large volume of data in order to discover new knowledge. However, knowledge discovery on just the most detailed and recent data does not reveal the long-term trends. Relational databases create new types of problems for knowledge discovery since they are normalized to avoid redundancies and update anomalies, which make them unsuitable for knowledge discovery. A key issue in any discovery system is to ensure the consistency, accuracy, and completeness of the discovered knowledge. We describe the aforementioned problems associated with the quality of the discovered knowledge and provide some solutions to avoid them.

Databases contain a variety of patterns, but few of them are of much interest. A pattern is interesting to the degree that it is not only accurate but that it is also useful with respect to the end user’s knowledge and objectives (Brachman et al., 1996; Bradley et al., 2002; Hand et al., 2001; Berry & Linoff, 2000; Piatetsky-Shapiro & Matheus, 1994; Silberschatz & Tuzhilin, 1995). A critical issue in knowledge discovery is how well the database is created and maintained. Real-world databases present difficulties as they tend to be dynamic, incomplete, redundant, inaccurate, and very large. Naturally, the efficiency of the discovery process and the quality of the discovered knowledge are strongly dependent on the quality of data.

To discover useful knowledge from the databases, we need to provide clean data to the discovery process. Most large databases have redundant and inconsistent data, missing data fields, and values, as well as data fields that are not logically related and are stored in the same data relations (Adriaans & Zantinge, 1996; Parsaye & Chingell, 1999; Piatetsky-Shapiro, 1991; Savasere et al. 1995). Subsequently, the databases have to be cleaned before the actual discovery process takes place in order to avoid discovering incomplete, inaccurate, redundant, inconsistent, and uninteresting knowledge. Different tools and techniques have been developed to improve the quality of the databases in recent years, leading to a better discovery environment. There are still problems associated with the discovery techniques/schemes which cause the discovered knowledge to be incorrect, inconsistent, incomplete, and uninteresting.

Most of the knowledge discovery has been done on operational relational databases (Sarawagi et al., 1998). Operational relational databases, built for online transaction processing, are generally regarded as unsuitable for rule discovery since they are designed for maximizing transaction capacity and typically have a lot of tables in order not to lock out users. In addition, the goal of the relational databases is to provide a platform for querying data about uniquely identified objects. However, such uniqueness constraints are not desirable in a knowledge discovery environment. In fact, they are harmful since, from a data mining point of view, we are interested in the frequency with which objects occur (Adriaans & Zantinge, 1996; Berry & Linoff, 2000; Bradley & Gehrke, 2002; Hand et al., 2001). Subsequently, knowledge discovery in an operational environment could lead to inaccurate and incomplete discovered knowledge. The operational data contains the most recent data about the organization and is organized as normalized relations for fast retrieval as well as avoiding update anomalies. Summary and historical data, which are essential for accurate and complete knowledge discovery, are generally absent in the operational databases. Rule discovery based on just the detailed (most recent) data is neither accurate nor complete.
