ABSTRACT
We use task-technology-fit model to develop an instrument for obtaining user evaluations of IT in health care. Our results indicate that task-technology fit along with individual characteristics have an impact on user evaluation of the IT in health care. We modify the original task-technology fit model for adequate domain coverage in health care industry. The contribution of our study is towards development and testing of an instrument for measuring user evaluations of IT in health care. The proposed model is successfully tested using a survey of 156 respondents from the eastern United States.

INTRODUCTION
Much has been written about end-user perceptions of IT (Davis, 1989; Baroudi, Olson, and Ives, 1986; Robey, 1979; Adams, Nelson, and Todd, 1992; Moore and Benbasat 1991). But few studies address user evaluations of IT in the health care industry. The tremendous growth of the use of IT increasingly has been felt by administrators in health care. Hospital administrators now recognize IT as a powerful tool for their organization to gain competitive advantage. The widespread use of IT by end-users reinforces the importance of gaining a more complete understanding of IT, and the factors related to successful quality control, cost containment, and staff scheduling.

A central focus of IT in health care has been directed to the factors associated with providing high-quality patient care (Margolis and Booker, 1992). Quality control has been viewed from a variety of perspectives and has had varying definitions and measures of success, including individual hospital and department quality assurance (Hetherington, 1982; Restuccia and Holloway, 1982). However, hospital industry experts feel that healthcare costs could be contained by billions of dollars each year if end-users were to use IT to improve quality using other measures (Margolis and Booker, 1992). Among these, electronic management and transmission of patient data and perceived end-user benefits have not been investigated rigorously. In this study, we develop and test an instrument to measure the end-user evaluation of IT in health care.

THE THEORETICAL FRAMEWORK
Task technology fit (TTF) model is a popular model for obtaining user evaluation of information systems. The TTF model is illustrated in Figure 1. The central premise for the TTF model is that “users will give evaluations based on the extent to which systems meet their needs and abilities” (Goodhue, 1995).

TTF model represented in Figure 1 is very general and using it for a particular setting needs special consideration. Among the three factors that determine the user evaluations of IS, technology is the most complex factor to measure in health care. Technology in health care is used for reporting, electronic information sharing and staff scheduling. Reporting is important in a health care setting because patient lives depend on accurate and timely information. There are four types of information that is reported in a health care facility. These four information categories are: scientific and technical information, patient-care information, customer satisfaction information and administrative information (Rodger, 1997). Scientific and technical information provides the knowledge base for identifying, organizing, retrieving, analyzing, delivering and reporting clinical and managerial journal literature, reference information, and research data for use in designing, managing, and improving patient-specific and departmental processes (JCAHO, 1995). Patient-care information is specific data and information on patient that is essential for maintaining accurate medical records of the patient’s medical history and physical examinations. Patient-specific data and information are critical to tracking all diagnostic and therapeutic procedures and tests. Maintaining accurate information about patient-care results and discharges is imperative to delivering quality health care (Bergman, 1993). Customer satisfaction information is information gathered on external customers such as patient and their family and friends. Customer satisfaction information is gathered from surveys and takes into account socio-demographic characteristics, physical and psychological status, attitudes and expectations concerning medical care, the outcome of treatment, and the health care setting (McLaughlin and Kaluzny, 1994). The administrative information that is reported in the health care facility is the information essential for formulating and implementing effective policies both at the organizational and departmental level. The administrative information is necessary to determine the degree of risk involved in

financing expansion of services (Duncan et. al, 1995). Functional 
departments within the health care facility must be able to access 
and report new information in order to respond properly to changes 
in the health care environment (Longest, 1990).

Information sharing and connectivity are increasingly im-
portant as the availability of external consultative services increase. 
Connectivity allows diagnoses to be made in remote locations using 
electronic means, and information sharing decreases the chances that mistakes will be made in a health care setting. Con-
nectivity in health care is integration of hardware, software, data-
bases and the networks (Rodger, 1997). Venkatraman and Zaheer 
(1990) were one of the first to introduce the concept of connectiv-
ity, even though they used a rather narrow bandwidth approach. In 
fact, E-mail was the only medium available on the leading edge of 
connectivity at the time Venkatraman and Zaheer (1990) made their observations about communicating with others via electronic means. Today, the concept of connectivity has taken on a broader 
meaning, especially in the context of health care. The medium is 
much richer today in terms of interactivity, temporal constraints, 
and bandwidth. The technological infrastructure of organizations is 
becoming increasingly complex (Henderson, 1990). More and 
more, information technology is being used to improve coordina-
tion of activities both within and across organizations (Cash and 
Konsynski, 1985). Computers and video networks are providing 
long distance health care through medical connectivity. Doctors, 
today, can interact with each other and ancillary medical person-
nel through e-mail, video and audio means. A difficult patient case 
in rural area can be given expert specialist attention simply by 
using “distance” medicine. Not only can patient records, text, docu-
ments be transmitted instantaneously via electronic means- but 
live video, X-rays, and other diagnostic parameters can be dis-
cussed in an interactive manner with live discussions weaving a 
web of competency never before witnessed in medical history. 
Connectivity leads to shared care that comprises the continued, 
coordinated and integrated activities of different people from dif-
ferent institutions applying different methods in different time 
frames, all in a combined effort to aid patients medically, psycho-
logically and socially in the most beneficial ways (Ellsasser et. al, 
1995).

Staff and equipment scheduling has received a lot of atten-
tion in operations research area. IT is used for scheduling for low-
ering the health care cost and improving effective utilization of 
physical and human resources. Scheduling using statistical, time 
series and regression analysis is conducted to achieve lower costs 
through rationing assets e.g., ambulatory service, and real time 
forecasting of resources (Ow et. al, 1989).

Other than technology, user evaluations of IT depend on task 
and individual characteristics. Task characteristics in health care 
can be measured as formal routine and adhoc assigned/non-rout-
tine tasks. Individual characteristics are measured by level of edu-
cation and orientation (clinical/administrative).

RESEARCH METHOD

Sampling Procedure
End-users from a pool of twenty health care facilities in the 
estern United States were contacted by telephone and invited to 
participate in the study. This region was selected for reasons of 
geographical proximity of the sample and, in many cases, the ex-
istence of personal contacts within the facilities. Fourteen out of 
the twenty facilities agreed to participate in the study. Five hun-
dred survey questionnaires were distributed (mailed and hand 
delivered) of which 167 were returned at the time of the data analy-

The results of the factor analysis indicated that technology construct is a multi-dimensional construct consisting of two dimensions measured as “IT for data analysis/reporting” and “IT for scheduling”. To measure the uni-dimensionality of each one of these two constructs, we ran a confirmatory factory analysis using LISREL. Figure 2 illustrates the results of the confirmatory factor analysis. The normalized goodness of fit index was 0.921 indicating that the two factors are unidimensional. The chi-square statistics was retained with the value of 55.728 and \( p=1.00 \).

The low reliabilities in task and individual characteristics factors make the measurement less reliable. Although we use task and individual characteristics in our analysis, we exercise care in interpreting the results.

DATA ANALYSIS PROCEDURE AND RESULTS

Multiple regression was performed to assess the contribution of IT for scheduling, IT for data analysis/reporting, task characteristics and individual characteristics on the user evaluations of IT in health care. Table 4 illustrates the results of the multiple-regression analysis.

CONCLUSIONS

This study represents the first development and test of an integrated model for measuring end-user evaluations of IT in the health care industry. The results have provided an instrument to measure the user evaluations of IT in health care. The study’s primary contribution was to development of an instrument, it has some limitations which should be addressed in further research: (1) Other variables may be added to the model as possible impacts on end-user evaluation of IT; (2) Present measures of end-user evaluations of IT may be replaced by more objective measures; and (3) The measures for the various constructs associated with end-user perceptions of IT may be improved by adding more items to measure the construct. Most importantly, it must be remembered that although the IT end-users surveyed in this study represented a wide variety of departments and health care institutions, they were drawn from a convenience sample and may not necessarily represent the entire population of IT end-users. Therefore, more empirical
research may be necessary before generalizing present results to IT end-users in other health care organizations. Each of these limitations represents an opportunity for further research in the area of end-user evaluations of IT in the health care industry.
