Bowling Green State University, USA

ABSTRACT

This chapter addresses the integration of additive manufacturing (AM) and welding technologies, highlighting their synergistic value in prototyping and production for automotive, medical, and aerospace industries. The integration of AM's ability to produce complex geometries with welding's strength, hybrid systems like Wire Arc Additive Manufacturing (WAAM) enable rapid design iteration, material savings, and scalable manufacturing. The research covers fundamental concepts, including AM processes and welding procedures, as well as material issues and integration process problems. Real-world applications demonstrate up to 40% lead time savings and 15–25% weight reduction. Statistical process control and non-destructive testing ensure compliance with standards like ISO/ASTM 52900. However, limitations like thermal management, high costs, and training gaps in the workforce persist.

1. INTRODUCTION

The combination of welding and 3D printing processes is an important leap in production; it introduces new avenues for prototyping and manufacturing in the automotive and aerospace industries, it also assists in manufacturing medical equipment. Additive manufacturing or 3D printing builds objects layer by layer; it

DOI: 10.4018/979-8-3373-1797-7.ch010

accommodates complex shapes and material utilization with efficiency that standard methods struggle to match (Gibson et al., 2021). Welding is a regular process used in bonding materials to each other, it makes structures strong and long-lasting by using heat, pressure, or a combination of the two in fusing and bonding the materials into unison (Kah et al., 2016). By combining these two processes, manufacturers are better placed to benefit from the design flexibility in using 3D printing with the reliability and strength of welded assemblies. This yields hybrid systems that address the challenges each method faces when used individually. This merger has yielded new methods like Wire Arc Additive Manufacturing (WAAM), which uses welding to deposit metal one layer at a time; it also includes hybrid models that merge 3D printing with welding to improve results (Williams et al., 2016).

All of these transformations are actually conducive to quick model making, where iteration and customization are essential in a hurry, they are also important in production, where quality control and scalability are of utmost importance. For example, organizations are using additive manufacturing along with welding to construct lightweight aircraft parts, durable car components, and customized medical implants for patients (Bandyopadhyay & Heer, 2018). However, there are still challenges like process integration, heat management, and material compatibility; therefore, additional research and development is needed (Ding et al., 2019). This chapter delves into how additive manufacturing (AM) and welding relate to each other, especially in making prototypes and products.

It discusses the basic principles of both technologies, explores their working together with examples and hybrid approaches, and discusses their practical effects in major industries. It discusses quality control, regulatory aspects, and limitations, providing a comprehensive account of how these technologies are working currently and what they can do in the future. This chapter consolidates contemporary industry practices and research to make the researchers, engineers, and manufacturers aware of the benefits and drawbacks of incorporating additive manufacturing (AM) along with welding (Seifi et al., 2017).

2. CONCEPTUAL REVIEW

2.1 Additive Manufacturing and Welding

Additive manufacturing and welding vary in purpose, but they both aim to build or improve physical objects by working attentively with materials. Additive manufacturing builds parts by depositing material in layers, as instructed by digital blueprints. It accommodates intricate designs and uses less material (Frazier, 2016). Welding refers to a process that combines materials, often metals or plastics, by the
